

DTE Platform — Ruthless Scope Cut (V1 → V3)

Mandate. Not to improve the design — to *cut it down*. Source of truth:

DTE Platform — Product & Domain Blueprint (DTE-Type-First).

Optimization target: **speed to first paying customer**, single deployment, single emisor, first commercial install, limited engineering.

Default answer to "should V1 have X?" is NO. A feature earns V1 only if the first customer legally cannot operate without it, or cannot be sold without it. Everything else waits.

0. The brutal filter (how every item was judged)

An item is **MUST HAVE (V1)** only if at least one is true:

1. **Legal blocker** — the customer cannot lawfully issue/cancel a document without it.
2. **Cannot-backfill** — skipping it now corrupts data forever (immutability, audit chain, evidence, IDs).
3. **Sale blocker** — the first customer literally will not pay without it.

If an item is merely *convenient*, *cleaner*, *future-proofing*, or *"a real product should have it"* → it is **not** V1.

The smallest sellable truth: one emisor can, through a UI, **issue a Factura and a CCF to a receptor, sign it, get an MH sello, survive the internet dropping (contingencia), cancel a mistake (anulación), hand the client a PDF, and prove all of it later (evidence + audit).** That sentence *is* V1. Everything in the blueprint that isn't in that sentence is suspect.

1. Release ladder (what each version unlocks)

Version	Theme	What it unlocks commercially
V1	Issue → sign → transmit → survive outage → cancel → prove	First paying customer can run their daily billing legally. Sell.
V1.5	Make it pleasant & complete for daily ops	NC/ND corrections, API for their POS/ERP, email delivery, tax-book export, alerts. Retain & expand the customer.
V2	Money & the full document spectrum	Receivables/payments, settlement, inbound reception, retención, export & remaining DTE types. Sell to bigger/more complex customers.
V3	Enterprise & multi-tenant	Multi-emisor, configurable approvals, advanced reporting, archival tiers. Sell to accounting firms & groups.

2. Master classification — by context

Legend: **MUST** = V1, **SHOULD** = V1.5, **NICE** = V2, **DEFER** = V3 (or never). Where an item splits, the row says so.

2.1 DTE Type Registry

Item	Class	Rel.	Ruthless rationale
Factura 01 • CCF 03 specs	MUST	V1	The two documents virtually every SV business issues daily.

Item	Class	Rel.	Ruthless rationale
			Without these there is no product.
Nota de Crédito 05 / Débito 06	SHOULD	V1.5	Corrections matter, but a fresh anulación + reissue covers it for launch. Add once the customer feels the pain.
CR 07, FEX 11, FSE 14, CL 08, CD 09, NR 04, Don 15	NICE / DEFER	V2/V3	Only build the type the <i>signed</i> customer actually uses. Don't pre-build the catalog.
Full declarative validation-rule engine	SHOULD	V1.5	V1 can hard-validate FE/CCF in code behind a thin interface. The <i>generic engine</i> is the right end state, not the launch state.
Schema versioning / effective-dating	MUST (minimal)	V1	Store which MH schema version each doc used. Cheap now, impossible to reconstruct later. Keep it; skip the fancy version-management UI.
Catalog data (units, tax codes, payment forms, geo)	MUST (static)	V1	Ship as pinned static reference data. A live, editable catalog-management surface is DEFER.

The honest compromise on "type-first." The blueprint's generic, spec-driven engine is the *correct architecture* — but building the full rule/schema engine before you have one paying customer is gold-plating. **V1 keeps the type-first *seam* (a spec object + schema-version stamping) but hard-codes FE/CCF behavior behind it.** You get the future-proofing without paying for the engine yet.

2.2 Issuance (core)

Item	Class	Rel.	Ruthless rationale
FiscalDocument aggregate + immutability after sign	MUST	V1	The product. Immutability is cannot-

Item	Class	Rel.	Ruthless rationale
			backfill.
ControlNumberSeries (gapless, per type/establecimiento/POS)	MUST	V1	Legal numbering. But single emisor = few series; no contention engineering needed yet.
Signing (JWS with issuer cert)	MUST	V1	No signature, no DTE.
Transmission to MH + sello capture	MUST	V1	Acceptance is the legal event.
TransmissionRecord append- only attempt log	MUST (minimal)	V1	Need attempt history for indeterminate- state reconciliation. Keep simple.
Receptor/Item snapshotting	MUST	V1	Immutability of issued facts. Cannot-backfill.
Indeterminate-state reconciliation (consulta)	SHOULD	V1.5	V1 can handle the rare ambiguous case manually. Automate once volume justifies.
Batch / bulk issuance	DEFER	V3	Single customer issues one at a time at launch.

2.3 Contingency

Item	Class	Rel.	Ruthless rationale
Sign-now / transmit-later + ContingencyEpisode + batch resubmit	MUST	V1	Unstable internet is the platform's entire premise, and contingencia is a legal regime. Non-negotiable even in V1.
Full contingency-type classification + auto- escalation on window breach	SHOULD	V1.5	V1 can use one default cause + a manual "resend batch" button. Refine later.

Do not cut contingencia from V1. It is tempting (it's complex), but a Salvadoran DTE product that dies when the internet blinks is unsellable and arguably non-compliant. Cut its *polish*, never its *existence*.

2.4 Invalidation & Substitution

Item	Class	Rel.	Ruthless rationale
Plain anulación (types 2 "rescindir" / 3 "otros")	MUST	V1	You must be able to kill a wrongly issued document. Simple, single-document flow.
Substitution saga (anulación type 1 + replacement, ordered)	SHOULD	V1.5	The orchestrated invalidate-and-replace is genuinely hard. For V1, "anular then issue a new one manually" is an acceptable workaround the user performs in two steps.

2.5 Parties / Counterparties & Catalog

Item	Class	Rel.	Ruthless rationale
Counterparty (receptor) records: tax identity, name, address	MUST (lean)	V1	Need someone to bill. Keep it a flat record; no per-role fiscal profiles yet.
Item/Product records: description, unit, price, tax code	MUST (lean)	V1	Need something to put on lines. Even ad-hoc free-text lines could work, but a basic item list speeds daily billing and sells better.
Price lists / multi-currency / per-role profiles	DEFER	V3	Single customer, single currency (USD). Pure over-modeling for V1.
Counterparty import / dedupe / merge tooling	NICE	V2	Manual entry is fine for the first customer's volume.

2.6 Document Intake (API + Manual + Approval)

Item	Class	Rel.	Ruthless rationale
Manual issuance UI (type-aware form)	MUST	V1	The first customer will operate by hand. This is the primary front door at launch.
API issuance	SHOULD*	V1.5	<i>Promote to MUST only if the first customer is buying because*</i> they integrate a POS/ERP. Otherwise defer — a public API contract is expensive to stabilize.
Approval workflow (compose → approve → issue)	DEFER	V3	A single small team trusts its biller. Approval is governance for orgs that don't exist yet. Pure overhead at launch.

2.7 Receivables, Payments & Settlement

Item	Class	Rel.	Ruthless rationale
Simple paid / unpaid flag on a document	NICE	V2	Even this is optional — the customer likely tracks payment in their accounting system today.
Full AR ledger, partial payments, statements	DEFER	V2	A whole commercial subsystem. Zero of it blocks issuing a legal DTE.
SettlementRun + CL/CD liquidation	DEFER	V2/V3	Niche, complex, third-party-commission territory. Only for customers who need it.

2.8 Inbound Reception (supplier DTEs)

Item	Class	Rel.	Ruthless rationale
Receive/validate/store supplier DTEs	DEFER	V2	Important for IVA crédito and retención — but it is the <i>other half</i> of the domain and

Item	Class	Rel.	Ruthless rationale
			blocks nothing about issuing. Cut entirely from V1.

2.9 Receptor Delivery

Item	Class	Rel.	Ruthless rationale
One hard-coded PDF representation + JSON download	MUST (1 template)	V1	The customer must hand/show <i>something</i> to their client. Ship exactly one decent layout.
Email delivery to receptor	SHOULD	V1.5	Expected, but "download the PDF and send it yourself" is a survivable launch gap.
Branded/multi-template designer, receptor portal	DEFER	V2/V3	Aesthetics and self-service. Zero launch value.

2.10 Evidence & Archive

Item	Class	Rel.	Ruthless rationale
Write-once EvidenceBundle (signed payload + sello + integrity hash)	MUST	V1	Cannot-backfill and legally existential. The signed JSON is the source of truth.
One-click inspection export	SHOULD	V1.5	V1 can export via a query/script when an inspection actually happens. The <i>data</i> must exist now; the <i>button</i> can wait.
Archival tiers / cold storage lifecycle	DEFER	V3	A 10-year-volume problem, not a year-1 problem.

2.11 Audit Trail

Item	Class	Rel.	Ruthless rationale
Append-only, hash-chained audit of state transitions	MUST	V1	Cannot-backfill. Cheap to do now (a few columns + a hash). Disproportionately expensive to add later.
Audit <i>browsing/search UI</i>	NICE	V2	Write the entries in V1; build the nice viewer later. SQL/export suffices early.

2.12 Access & Roles

Item	Class	Rel.	Ruthless rationale
Auth + 2 roles (owner/admin, biller)	MUST (minimal)	V1	Someone logs in and bills. That's it.
Full role matrix (Approver, Accountant, Auditor, Service Acct)	SHOULD/NICE	V1.5/V2	Add roles as the features that need them arrive (e.g., Service Acct with API, Approver with approvals).
Policy layer (value thresholds, type/establishment scoping)	DEFER	V3	Governance for multi-user orgs. Not for one biller.
Tenancy seam (emisor boundary in the data model)	MUST (seam only)	V1	Keep the emisor key on data even with one emisor — it's nearly free and prevents a V3 rewrite. But build single-emisor UX .

2.13 Cross-cutting operational items

Item	Class	Rel.	Ruthless rationale
Certificate expiry alert	SHOULD	V1.5	Cheap, and an expired cert = cannot bill = catastrophic. Strong candidate to pull <i>into V1</i> if a day's work. Otherwise earliest V1.5.

Item	Class	Rel.	Ruthless rationale
Rejection / stuck-document notifications	SHOULD	V1.5	V1 surfaces status in the UI; push alerts can wait.
Webhooks to integrators	NICE	V2	Pairs with the API. No API consumer at launch → no webhooks.
Tax books (Libro de Ventas / Compras) export	SHOULD	V1.5	Monthly tax need. A CSV/Excel export of issued docs covers it; full Libro de Compras needs inbound reception (V2).
Reporting / dashboards / analytics	NICE/DEFER	V2/V3	A list view with filters is enough at launch.
Multi-emisor operation	DEFER	V3	Explicitly out by assumption. Only the data seam survives in V1.

3. The V1 cut list — what we drop, and why it's safe

Dropped from V1	Why postponing it does not damage the product
API issuance & webhooks	The first customer bills through the UI. A premature public API is an expensive, hard-to-change contract.
Approval workflow	One trusted biller needs no internal gatekeeping. It's org governance for orgs that don't exist yet.
Receivables / payments / settlement	An entire commercial subsystem that blocks no legal issuance. The customer already tracks money elsewhere.
Inbound reception	The other half of the domain. Needed for IVA crédito later — not to issue today.
NC/ND, CR, FEX, FSE, CL/CD, NR, donación	Build the type the signed customer uses. Corrections survive on anulación + reissue until V1.5.
Substitution saga	Replaced by a manual two-step (anular, then issue new) that the user performs deliberately.

Dropped from V1	Why postponing it does not damage the product
Generic validation/schema engine	Hard-coded FE/CCF validation behind a thin spec seam delivers the same launch outcome.
Multi-emisor, policy layer, full RBAC	Single emisor, single team. Keep only the data seam; build single-emisor UX.
Email delivery, branded templates, receptor portal	One PDF + JSON download lets the customer fulfill their obligation manually.
Inspection-export button, audit UI, dashboards, archival tiers	The <i>data</i> (evidence, audit chain) exists in V1; the <i>tooling</i> over it is added when first needed.

The one rule that protects all this cutting: anything *cannot-backfill* stays in V1 even if unglamorous — immutability, snapshots, evidence bundle, audit hash chain, schema-version stamping, the emisor data seam, and gapless control numbers. Everything else is a feature you can add *on top of* correct data later. We cut features, never data integrity.

4. V1 scope fence (definition of done)

In: single emisor; UI-only; FE 01 + CCF 03; manage receptors & items (lean); draft → validate → sign → transmit → sello; contingencia (sign-now/transmit-later + manual batch resend); plain anulación; one PDF + JSON; evidence bundle; hash-chained audit; cert handling (use only); login with owner/biller.

Out (everything else): API, webhooks, approvals, NC/ND and all other types, substitution saga, receivables/settlement, inbound reception, email/templates/portal, reporting/dashboards, multi-emisor, policy/RBAC depth, generic rule engine, archival tiering, audit/inspection UIs.

Pull-in candidates (only if each is < ~1 day): certificate-expiry alert; a CSV export of issued documents.

5. Honest risks of this cut (so the decision is informed)

Cut	Risk if the first customer turns out to need it	Mitigation
NC/ND	A customer with frequent post-issue corrections will feel friction using anulaci3n+reissue.	Qualify this during the sale. If they correct often, pull NC into V1.
API issuance	If the buyer is integrating a POS/ERP, UI-only is a dealbreaker.	This is the single biggest "know your first customer" question. Confirm before locking V1.
Email delivery	Manual "download & send" annoys high-volume sellers.	It's a fast V1.5; acceptable launch gap for a first design partner.
Tax-book export	Monthly filing pain shows up ~30 days post-launch.	Ship a basic CSV in V1.5 before their first filing cycle closes.
Cert-expiry alert	An expired cert silently halts all billing.	Strongly consider pulling the alert into V1; it's cheap insurance against a catastrophic outage.
